## Introduction

The goal of this project is to ensure the security of the Bay of Biscay by detecting any intruder entering this maritime area. A group of robots, equipped with GPS, are being used thanks to specific algorithms and a particular monitoring strategy.

In order to proceed with the project, the following working hypotheses are considered :

- The simulation can be done in a two-dimensional world ;
- Intruders will have a constant given velocity throughout the simulation ;
- Every surveillance robot has a detection range of  $d_i$  within which an intruder is necessarily detected ;
- The safe zones are as a group of rectangles where the intruder can not be.

Two deliverables will be delivered :

- The first one is a theoretical simulation written to a large extent in Python 3.0 which will allow to determine whether or not the used algorithms are relevant ;
- The second one is a practical simulation using some buggies robots available in the robotics group of ENSTA Bretagne.

# Chapitre 2

## Secure zone processing

### 2.1 Introduction to interval analysis

### 2.2 Secure zone estimation with interval analysis

#### 2.2.1 Basics and Usefulness of Interval Arithmetics

Normal solver equation are efficient with linear sytems but in a real environment

#### 2.2.2 Thick Functions

Introduce the concept of MAYBE

#### 2.2.3 Special Test for Gascogne Surveillance

We found a test to determine if a box is inside the secure zone covered by one  
Differente result In testing :

Symbol	Meaning
0	Box is not in the Secure Zone
1	Box is in the secure zone
?	Box may be in the secure zone
[0, ?]	Box may be in the secure zone
[ ?,1]	Box may be in the secure zone
[0,1]	Box may be in the secure zone or out

Test1/Test20	0	1	?	[0, ?]	[ ?,1]	[0,1]
0	0	1	?	[0, ?]	[ ?,1]	[0,1]
1		1	1	1	1	1
?			?	?	[ ?,1]	[ ?,1]
[0, ?]				[0, ?]	[ ?,1]	[0,1]
[ ?,1]					[ ?,1]	[ ?,1]
[0,1]						[0,1]

---

**Algorithm 1** Is  $\mathbf{X} \subseteq \mathbb{S}$ ,  $\mathbb{S}$  = Secure Zone and  $\mathbf{X} \in \mathbb{R}^2$

---

**Require:**  $X, range$  (reach of boat),  $m$  (position of boat)

$Xmx \leftarrow \max([0, 0], \text{sign}((X[0] - m[0].ub()) * (X[0] - m[0].lb())) * \min((X[0] - m[0].lb())^2, (X[0] - m[0].ub())^2))$

$Xmy \leftarrow \max([0, 0], \text{sign}((X[1] - m[1].ub()) * (X[1] - m[1].lb())) * \min((X[1] - m[1].lb())^2, (X[1] - m[1].ub())^2))$

$Xm \leftarrow Xmx + Xmy$

$Xp \leftarrow \max((X[0] - m[0].lb())^2, (X[0] - m[0].ub())^2) + \max((X[1] - m[1].lb())^2, (X[1] - m[1].ub())^2)$

$Xub \leftarrow Xp | Xm$

**if**  $Xub \cap [0, range^2] = \emptyset$  **then**

**return** OUT

**else if**  $Xub \subseteq [0, range^2]$  **then**

**return** IN

**else**

**if**  $range^2 - Xp.ub() < 0$  **then**

**if**  $Xm - range^2 \subseteq [-\infty, 0]$  **then**

**return** MAYBE

**else**

**return** UNKNOWN2

**end if**

**else**

**return** UNKNOWN

**end if**

**end if**

---

---

**Algorithm 2** Is  $\mathbf{X} \subseteq \mathbb{S}$ ,  $\mathbb{S}$  = Secure Zone and  $\mathbf{X} \in \mathbb{R}^2$

---

**Require:**  $X, range$  (reach of a boat),  $\{m\}$  (list of position of boats)

$R \leftarrow \text{Algorithm1}(X, range, \{m\})$

**if** IN  $\subset R$  **then**

**return** IN

**else if** UNKNOWN  $\subset R$  **then**

**return** UNKNOWN

**else if** MAYBE  $\subset R$  **then**

**return** MAYBE

**else if**  $\forall r \in R, r = \text{OUT}$  **then**

**return** OUT

**else**

**return** UNKNOWN

**end if**

---

## 2.3 Mesh to boxes functions

## 2.4 Erosion functions

## 2.5 Global Sivia algorithm

## 2.6 Results

**Répartition des bateaux** Dans un premier temps, nous avons penser à répartir les bateaux avec un espacement régulier selon l'abscisse curviligne de l'ellipse. Cette méthode étant finalement très difficile à mettre en place d'un point de vue mathématique et algorithmique, cette solution a été abandonnée. Il aurait fallu, pour se faire, approximer les intégrales de Wallis par un développement limité assez complexe, ce qui implique un temps de programmation important et un temps de calcul beaucoup trop long pour une simple étude de faisabilité. C'est pour cela que nous avons décidé de nous orienter vers un retard angulaire sur chacun des robots. Ainsi, chaque robot suit le robot précédent avec un retard angulaire fixe dépendant du nombre de robots parcourant l'ellipse. Cela implique que les robots vont être d'autant plus proches les uns des uns qu'il sont près des apogées de l'ellipse, et d'autant plus éloignés aux périgées. Néanmoins, malgré la non-linéarité du placement des robots, nous n'avons pas de rupture de la zone de détection. En effet, comme les robots vont plus vite aux périgées, la trace qu'ils "laissent" est plus grande, et inversement aux apogées. De ce fait, on peut garantir la sécurité de la zone à surveiller, même si les robots ne sont pas régulièrement espacés.

# Chapitre 3

## Robots regulation

### 3.1 Regulation

### 3.2 Regulation of the robot pack

Two methods have been studied and implemented to regulate the pack of robots. The first is a method by artificial potential field, robust and easy to debug. This method was chosen to regulate the real robots on the play field. The second method is a method of looping linearisation, very efficient. This method was chosen for the simulation because its integration in a simulation is easier than on robots.

#### 3.2.1 Artificial potential field

Let  $p_{robot}$  be the position of our considered robot, let  $p_{target}$  and  $v_{target}$  be the position and speed of the target we want the robot to reach. We can consider the robot and the target as two particles of opposite charge, and then compute the potential field between them. In case of obstacles, we can consider them as particles of same charge than the robot's. The potential field method calculate the instantaneous speed vector  $w(p_{robot}, t)$  the robot need to reach (or at least follow) the target. To compute that speed, we use the potential  $V$  between the robot and the target :

$$V(p_{robot}) = v_{target}^T \cdot p_{robot} + \|p_{robot} - p_{target}\|^2$$

And compute the gradient of that potential to find the order  $w(p_{robot}, t)$  :

$$w(p_{robot}, t) = -grad(V(p_{robot})) = -\frac{dV}{dP}(p)^T$$

So :

$$w(p_{robot}, t) = v_{target} - 2 \cdot (p_{robot} - p_{target})$$

For  $w$ , we compute the order speed and course :

$$\bar{v} = \|w\|$$

$$\bar{\theta} = \tan\left(\frac{w_y}{w_x}\right)$$

A proportional regulation compute the command  $u_v$  and  $u_\theta$  which will be used to control the robot.

$$u_v = Kp_v \cdot (\bar{v} - v_{robot})$$

$$u_\theta = Kp_\theta \cdot (\bar{\theta} - \theta_{robot})$$

$u_v$  and  $u_\theta$  are saturated to avoid a surcharge of the actionners.

### 3.3 Evolution of the elliptic trajectory

### 3.4 Conversion of the order to a PWM command

# Chapitre 4

## Implementation with buggy robots

### 4.1 Matériel

Pour la réalisation d'une simulation sur des robots, nous avons dû implémenter une architecture afin de permettre à notre programme de gérer d'une part nos robots et d'autre part de voir si le résultat théorique correspond aux résultats expérimentaux.

Nous aboutissons au final à l'architecture suivante :

FIGURE 4.1 – Architecture mise en place pour la simulation sur robot char.

## 4.2 GPS Sentence Analysis

*Pierre JACQUOT*

In order to get the GPS coordinates of each robots we decided to use the *GPRMC* sentence send by the GPS's emitter. The exemple below show the structure of a *GPRMC* sentence :

081836	A	3751.65	S	14507.36	E	000.0	360.0	130998,01	011.3	E*62
UTC	Data sta- tus	Latitude	N or S	Longitude	E or W	Speed (knots)	Track made good	UT Date	Magnetic Variation	E or W and Check- sum

The most valuable data are the latitude, the longitude, the speed over ground (in knots) ant the time stamp. In order to get those different data, we used the python package *pynmea*, which allows to easily get and parse a GPS sentence.

However, the longitude and latitude obtained using this specific sentence have a particular structure that we had to changed to make them easier to manipulate and compute in our algorithm. The exemple below show how the longitude and latitude are originally formatted :

- Longitude : *12311.12,W* which means Longitude 123 degree. 11.12 min West
- Latitude : *4916.45,N* which means Latitude 49 degree 16.45 min North

In order to ease the computation, our program automatically convert the longitude and latitude in degrees, take into account the cardinal direction associated with each coordinates. These cardinal directions North and South for the latitude and East and West for the longitude, let us know respectively on which side of the Greenwich (or prime) meridian we are located and on which side of the equator we are located. As a matter of fact, we will have in Brest a "negative" latitude and a positive longitude, due to our positioning regarding the equator and Greenwich meridian.

Our program not only give the coordinates in degrees but also convert them into UTM (Universal Transverse Mercator) coordinates. This new set of coordinates allow a localisation of the robot in a flat local coordinates system and maybe more easy to use as they are just decimal numbers. The UTM system itself, consist in a subdivision of the world in different sectors which can be consider as flat, and with a specific system of coordinates. The figure below show the subdivision of France :

FIGURE 4.2 – Secteur UTM

This figure show that we are currently in the sector 30. Whereas,in order to compute UTM coordinates, we need first to choose a geodesic system representing the Earth. For this project we chose the WGS-84 system which is most commonly used.

## 4.3 Structure du code

Quatre scripts python : GPS2.py, commande.py, testserial.py et ServeurN.py

The code which have been implemented for this part of the project can be sum up with the following picture 4.3 :

As you can see, there are 5 main script that are used in order to run the whole program.

## 4.4 Résultats

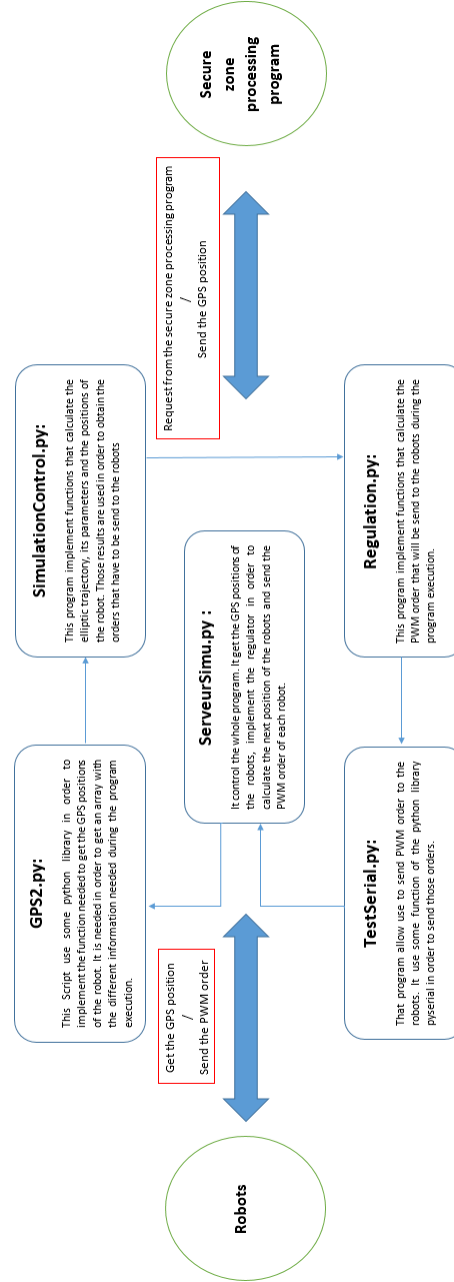

FIGURE 4.3 – Architecture of the program which control the regulation of the robots.
